The Effect of Community Reintegration on Rates of Recidivism: A Statistical Overview of Data for the Years 1971 Through 1983

This The Research Division of the Massachusetts Department of Correction routinely collects and publishes on an annual basis In these reports a series of descriptive variables on all individuals released from Massachusetts Correctional Institutions is correlated with rates of recidivism. Comparisons between current findings and trends discerned in Additionally, comparisons between specific correctional institutions of varying security levels and comparisons between varying modes of correctional programming are also made. The state correctional institutions include maximum, medium and minimum security facilities as well as state run prerelease centers and sub-contracted privately operated report attempts to draw together data generated from the recidivism studies of the past 13 years and to present a summary From these studies data are currently available for the releasee cohorts for the years 1971 through 1983. statistical overview of the findings. data on rates of recidivism. prior studies are made. halfway houses.

The annual statistical monitoring of recidivism data since the year 1971 has led to the detection of a number of significant trends occuring within the Massachusetts correctional system. Dominant among these trends was the occurrence of a systematic reduction in the recidivism rates from 1971 through to 1978. For example, in the year 1971 the recidivism rate for the combined population of state prison releases was 25%; in 1973 it had dropped to 19%; and in 1976 it had dropped to 16%. By 1977, the recidivism rate was 15%. Later data, however, revealed that a reversal had occurred in this historical trend. The 1979 and 1980 releasee populations represented the first statistically significant increase in recidivism rates in a nine year period. However, 1981 through 1983 data have shown a modest but consistent drop in recidivism rates. second major trend concerned the home furlough program in the Massachusetts correctional system, a program begun in and expanded subsequent to the year 1971. Recidivism studies demonstrated that inmate participation in the furlough program revealed that those individuals who had experienced a furlough prior to release from prison had significantly lower rates of recidivism than did individuals who had not experienced a furlough prior to release. When selection factors were controlled, the relationship remained positive. This trend continued in a consistent pattern for the eleven successive years for which data were may be an important variable in accounting for the systematic reduction in recidivism rates occurring in Massachusetts. available. Recidivism studies have also revealed that participation in prerelease programs prior to community release leads to reduced rates of recidivism. Again, when selection factors were controlled the relationship remained constant.

among institutions in descending level of security and size. Analyses revealed that individuals released from prison directly from recidivism than did individuals released directly from a maximum security institution. Again, this relationship held even when A final documented trend that has emerged from the recidivism studies focused on the process of graduated movement medium or minimum security institutions (including prerelease centers and halfway houses) had significantly lower rates of selection factors were controlled. When follow-up periods were extended from one to two and then to five years, the above findings with respect to furloughs, prerelease centers, and security level of releasing institution remained constant. The major findings of the research were collectively interpreted as tentative evidence of a positive effect of the That is, correctional programs operating in the Massachusetts reintegrative community based correctional programming.

institutions in descending levels of security and size along with the awarding of increased increments of community contacts is the graduated societal reintroduction of the offender. This is accomplished through a series of movements among system which are geared to maintain, to establish, or to reestablish general societal links such as family, economic, political, and social roles may be associated with a subsequent reduction in recidivism. Also associated with the reduction in recidivism through participation in furloughs, education release, and work release programs. The above conclusions hold through the documented trend of increased recidivism and the more recent drop in the rates. Despite the fluctuations in overall recidivism, participation in reintegration programs remains associated with lower rates of recidivism.^I

TA bibliography of the research data referred to in this summary is presented at the end of this report.

Method

Definition of Recidivism: A recidivist was defined as any subject who was returned to a state or federal correctional institution, to a county house of correction, or to a jail for a period of 30 days or more during the period of follow-up. For each of the releasee cohorts a one year time criterion constituted the follow-up period. That is, each subject was followed for one full year after release to the community. In addition, two relesee cohorts (1973 and 1976 releases) used follow-up criteria varying from one to five years. Follow-Up Period:

Variables Collected: For the analysis that follows in this report, four categories of variables were collected: (1) current offense commitment variables; (2) personal background characteristics variable; (3) criminal history variables; and (4) recidivism Base Expectancy Rates: At several important junctures in the analysis, it is necessary to conduct a test for possible differences in the recidivism risk potentials of two populations. Such a test is important when separately comparing yearly cohorts as well as variables. Data were collected from the files of the Department of Correction, the Board of Parole, and the Board of Probation. when comparing sub-populations within these cohorts. Base Expectancy tables are used in these studies for this purpose. 2

ZFor a copy of the specific base expectancy table, a description of the method of construction, and a listing of variables utilized see: LeClair, Daniel P., "Development of Base Expectancy Prediction Tables for Treatment and Control Groups in Correctional Research," DOC Report No. 134, August, 1977.

Dallas Miller, Research Assistant, was responsible for updating this report by adding data for 1981 - 1983 releases.

Format of the Report

The report is divided into three sections. Section I provides a general overview of the recidivism data for a thirteen year span. Additionally, data on the specified individual trends are also provided in this section. Section II presents data on trends for which a control for program selection biases has been performed. That is, Base Expectancy Tables have been utilized to construct expected rates of recidivism. Data for each of the trends are therefore analyzed in terms of expected vs. actual results and tests of significance are performed.

Section III reviews the data patterns discerned in terms of extended follow-up periods. It addresses the question of whether or not trends uncovered in a one year follow-up remain valid when the follow-up is extended up to five years. At the end of the report a bibliography is provided which contains a listing of all the published recidivism reports that this statistical overview summarizes. Copies of these reports are available at the Department of Correction. SECTION ONE

SECTION TWO

DATA ON TRENDS, CONTROLLED FOR SELECTION FACTORS

Data on Trends, Controlling for Selection Processes

Collectively, the data presented in Section One of this report provide a foundation which supports the proposition that the this report use of the community reintegration model is associated with a reduction in recidivism. Such a proposition remains tentative, Therefore, Section Two of reexamines the data on recidivism trends from the standpoint of controlling for program selection biases. however, pending the resolution of issues regarding program selection processes.

When possible, the most ideal method of evaluating the effects of a particular correctional treatment program is to impose treatment (control) groups would occur administratively as part of program operation. This allows the researcher to have confidence that the selection process at the time of intake does not bias the treatment sample. An uncontrolled selection process an experimental design at the initial stage of program development. The random allocation of subjects into treatment and nonalways is subject to the criticism that less serious offender risks, in terms of recidivism outcome, have been chosen for treatment. Thus, if and when treatment effects are demonstrated, the researcher is faced with the criticism that the treatment group consisted of good risks who would have done well with or without treatment. Nevertheless, more frequently than not the random assignment of subjects to treatment and control groups is not possible in If unanticipated vacancies suddenly occur in programs and the administrator, conscious of the costs of resources the correctional setting. One reason for this situation is that the program administrators frequently insist upon having a say in who is and is not admitted to their programs. A second reason, also an administratively related one, is that random assignment of subjects can be cumbersome and difficult to operate. It often ties the administrator's hands when faced with practical day to day decisions. unused, cannot find enough individuals immediatley available in the treatment pool the temptation is often great to select eligible subjects from the control pool. third inhibition to the use of random allocation is the inmate. Often inmates prefer to choose or reject involvement in treatment programs for a variety of personal reasons, such as: the program may be located too far away from their families thus preventing normal family visitation patterns; the inmate may know of an individual already in the program with whom he has a serious "beef" and would therefore be placed in danger; or the inmate may be reticent about leaving a known and secure social status at the present site and thus prefer to remain. A final inhibition to random alloccation is a moral or civil rights reason. Should inmates be denied treatment simply for the In many correctional systems, especially in our time of growing conscciousness of inmate rights, administrators as well as inmates would answer that to do so would be to deny basic inmate rights--the right for treatment and the right of choice of treatment. purposes of research?

Because of the many difficulties of utilizing random selection at the point of intake into the treatment programs alternative Some researches use matching techniques whereby the control group is constructed by matching background and criminal history characteristics with the treatment sample. A second technique has been to go back to a prison population prior to the existence of the treatment program and select inmates who would have been eligible for the program had it existed utilizing the population thus selected as a control group. A third technique is to utilize Base Expectancy Prediction strategies are often used. Tables. In correctional research, the Base Expectancy Table has been developed as a device whereby an estimation is made of the varying degrees to which individuals in a given prison population, or sub-group such as a particular treatment group, are at risk of

groups. The basis for the assignment of individuals into the appropriate risk group is determined on the experience of a separate known. Background information known prior to release is collected on this separate population and these items are correlated with the known outcome criteria-subsequent criminality or recidivism. Those items found to have the most predictive value are the individual items alone. At this point, the treatment sample (whose outcome criteria is not yet known) is divided into the same risk categories and an expected outcome rate is determined. The degree to which the expected rate of the treatment group continuing their criminal careers subsequent to release. It is a classification technique in which individuals are placed in risk population of prisoners not receiving that specified treatment and for whom criminal behavior subsequent to release is already combined into a table whose resultant interaction effects are believed to constitute a more powerful predictive instrument than approximates the actual rate of the control group determines the degree to which non-random selection has occurred. Additionally, if persons to be given various treatments are classified according to the risks that would have been expected After appropriate statistical tests for differences are computed, a judgement can be made as to whether or not the treatment program appears to before treatment began, a base line is formed against which the outcomes of treatment can be assessed. The risk estimate for treatment is completed and after the subsequent follow-up period in the community occurs, data on the Actual Outcome Rate are reduce the Actual Outcome Rate below the Expected Outcome Rate and thus measure the effectiveness of the program under each of the individuals in the treatment sample is combined to form an Expected Outcome Rate for the entire sample. At this point, the Expected Outcome is compared to the Actual Outcome. collected and determined. study. The data presented in the following section summarize a series of research studies that examine selection issues in the

It should be noted that the analyses have included only the males in the release-Each of the studies utilizes the Base Characteristics of male and female populations were felt to be sufficiently divergent to warrant separate Base Expectancy tables. However, the female populations were too small for table construction and validation purposes. material associating lower recidivism with participation in reintegration programming. Expectancy methodology discussed above. populations.

Therefore, the reader is alerted to the fact that the samples that follow are slightly lower in number than the similar material presented in Section One. These difference are solely the result of the exclusion of the female populations (usually less than 10% of the total sample) The first research study that controlled for selection facctors in the assignment of individuals to reintegration programs was related to participation in two prerelease centers - Boston State and Shirley Prerelease. The research evaluation resulted in two First, it was found that individuals who had completed the combined prerelease programs under study had significantly lower rates of recidivism than a control group of similar types of inmates who had not participated in a prerelease program and a significantly lower actual recidivism rate than their derived expected recidivism rate. Secondly, a series of inmate types which seem to be disproportionatey helped by prerelease program participation was tentatively identified. summarized in Table 8. major findings.

second study looked at Home Furlough Program participation during the years 1973 and 1974. The research provided initial supportive evidence that participation in Furlough Programs reduces the probability that an individual will recidivate upon Analysis indicated that the determined reduction in recidivism was due to the impact of the furlough program and not simply to the types of inmates who were selected for furloughs. These results are summarized in Table 9. release from prison.

The third study included in this section, summarized in Table 10 focused on the combined participation in both furlough and prerelease programs and controlled for selection factors. Results showed that the greater the participation in the model, the lower the recidivism rate.

selection factors were controlled. The results presented in Table 11, were similar to the other studies. That is, participation in The final study in this section graded the level of security of the releasing institution with the level of recidivism. Again, the reintegration model is associated with reduced recidivism even when selection factors are controlled.

Table 8

Expected Rates of Recidivism Compared to Observed Rates, Boston State and Shirley Releases During the Years 1972 and 1973

ample	Expected Recidivism Rate	Observed Recidivism Rate	Probability Level

SECTION THREE

OVERVIEW OF RECIDIVISM DATA, EXTENDED FOLLOW-UP PERIODS

Trend Discerned Through Extended Follow-Up Periods

Data presented in sections one and two of this report incorporate a definition of recidivism that utilizes a one year follow-Though subject to limitations, the one year follow-up period used in this definition allows planners and For example, many of the individual program components of the reintegration model had been federally funded for experimental trial purposes and were The series of one year follow-up studies allowed timely input, and thus relevant research data were available in the decisionmaking processes, leading both to an expansion of the reintegration programs and to the permanent state funding of these planned for pick up by permanent state funding at a later date if and when programmatic effectiveness could be demonstrated. administrators to receive feedback in a reasonable time frame for the deccision-making process. criterion. programs.

results found using a one year follow-up period become changed or reversed when the follow-up period is extended. Such concerns have prompted the National Advisory Commission of Criminal Justice Standards and Goals to recommend a three year follow-up doubt on the validity of the overall research findings. This prompted replications of some of the earlier studies of prison releases In studying recidivism, however, correctional researchers have pointed to the problem of "cross-over effects" whereby period as a response to this problem. Therefore, a concern existed that the limitations of the one year follow-up studies cast replication attempt involved a two year follow-up of releases in the year 1973 (LeClair, 1976). In this study no evidence of "crossover effects" was found. The major findings from the two year follow-up analysis fully supported the original one year follow-up A second replication involved a five year follow-up of the releases in the year 1973 (LeClair, 1981). Again the major which used a one year follow-up to see if emerging trends had remained consistent after additional years of follow-up.

findings of the former one and two year follow-up studies remained consistent. But because only a small percentage of the viewed as tentative. For this reason a second five year follow-up study was conducted using the population of releases in the year 1976 (LeClair, 1983). For the 1976 releases, more than 50% of the sample had been involved in the reintegration model programming. Analysis revealed that all trends previously identified remianed unchanged upon extension to five years of followreleases in the 1973 sample had participated in reintegration programs (approximately 10% of the sample), the results were up, thus denying a significant role to "cross-over effects" in the Massachusetts research.

Table 12
